

Shva Full-stack Developer Interview Task

Dear Candidate,

We're excited to see your skills in action! Below is your take-home task for the Shva full-stack developer interview.

At Shva, we deal with credit operations, processing, and financial data. For this task, you will build a **Transaction Approval Simulator**. Please follow the instructions carefully and let your technical skills shine.

Project Overview: You are required to create a new web project using **React**, **.NET (C#)**, and **MSSQL**. The task is to implement the UI and backend functionality based on the attached Figma design.

Task Requirements:

1. Frontend (React):

- **Responsiveness:** The application must be fully responsive, working smoothly on various screen sizes.
- **UI Implementation:** Recreate the provided Figma layout.
- **State Management:** Properly manage the state for the selected region, time, and the list of approved transactions.

2. Backend Functionality (.NET Web API):

- **RESTful API:** Develop a clean and scalable RESTful API using .NET (C#) to handle the frontend requests.
- **Business Logic:** Create an endpoint to submit a transaction simulation.
 - o **Rule:** A transaction is only "Approved" if the submitted time falls within the standard banking hours (08:00 to 18:00) of the **selected region**. Your backend must accurately determine what the *local time* was in the selected country (e.g., Israel, France, USA, Japan) at that exact moment. If it falls outside this window, it is "Rejected".
- **Database (MSSQL):** Store all submitted transactions (both approved and rejected) in an MSSQL database. Use Entity Framework Core (or a micro-ORM like Dapper, based on your preference).

- **Retrieval:** Create an endpoint to fetch only the "Approved Transactions" to display in the bottom cards.

Deliverables:

- A link to a **GitHub repository** containing the code for the project. Include clear instructions in the README.md on how to set up the database and run the application.
- A short **video demonstration** (e.g., Loom) showing the functionality of the app.

Bonus Points (Optional):

- **Containerization:** Running client, server, and database with a single command (e.g., using Docker Compose).
- **Localization (ENG/Hebrew):** Support switching between English and Hebrew using the top-right toggle. Implement RTL and LTR layout support based on the selected language. (No need to change the text inside the illustrations).
- **Authentication:** Basic User authentication (Login/Signup).

Next Steps:

After reviewing your submission, the next stage will be a Live Coding interview. We will use this project as a base to discuss your architectural decisions and implement a new piece of business logic together.

The rest is up to you. Show us what you can do! Good luck!
